

Chapter 17:

The Standard Template Library

17.1

Introduction to the Standard Template Library

The Standard Template Library

- **The Standard Template Library (STL):** an extensive library of generic templates for classes and functions.
- **Categories of Templates:**
 - **Containers:** Class templates for objects that store and organize data
 - **Iterators:** Class templates for objects that behave like pointers, and are used to access the individual data elements in a container
 - **Algorithms:** Function templates that perform various operations on elements of containers

17.2

STL Container and Iterator Fundamentals

Containers

Sequence Containers

-  Stores data sequentially in memory, in a fashion similar to an array

Associative Containers

-  Stores data in a nonsequential way that makes it faster to locate elements

Containers

Table 17-1 Sequence Containers

Container Class	Description
<code>array</code>	A fixed-size container that is similar to an array
<code>deque</code>	A double-ended queue. Like a <code>vector</code> , but designed so that values can be quickly added to or removed from the front and back. (This container will be discussed in Chapter 19.)
<code>forward_list</code>	A singly linked list of data elements. Values may be inserted to or removed from any position. (This container will be discussed in Chapter 18.)
<code>list</code>	A doubly linked list of data elements. Values may be inserted to or removed from any position. (This container will be discussed in Chapter 18.)
<code>vector</code>	A container that works like an expandable array. Values may be added to or removed from a <code>vector</code> . The <code>vector</code> automatically adjusts its size to accommodate the number of elements it contains.

Containers

Table 17-2 Associative Containers

Container Class	Description
<code>set</code>	Stores a set of unique values that are sorted. No duplicates are allowed.
<code>multiset</code>	Stores a set of unique values that are sorted. Duplicates are allowed.
<code>map</code>	Maps a set of keys to data elements. Only one key per data element is allowed. Duplicates are not allowed. The elements are sorted in order of their keys.
<code>multimap</code>	Maps a set of keys to data elements. Many keys per data element are allowed. Duplicates are allowed. The elements are sorted in order of their keys.
<code>unordered_set</code>	Like a <code>set</code> , except that the elements are not sorted
<code>unordered_multiset</code>	Like a <code>multiset</code> , except that the elements are not sorted
<code>unordered_map</code>	Like a <code>map</code> , except that the elements are not sorted
<code>unordered_multimap</code>	Like a <code>multimap</code> , except that the elements are not sorted

Container Adapters

Table 17-3 Container Adapter Classes

Container Adapter Class	Description
<code>stack</code>	An adapter class that stores elements in a <code>deque</code> (by default). A <code>stack</code> is a last-in, first-out (LIFO) container. When you retrieve an element from a <code>stack</code> , the <code>stack</code> always gives you the last element that was inserted. (This class will be discussed in Chapter 19.)
<code>queue</code>	An adapter class that stores elements in a <code>deque</code> (by default). A <code>queue</code> is a first-in, first-out (FIFO) container. When you retrieve an element from a <code>stack</code> , the <code>stack</code> always gives you the first, or earliest, element that was inserted. (This class will be discussed in Chapter 19.)
<code>priority_queue</code>	An adapter class that stores elements in a <code>vector</code> (by default). A data structure in which the element that you retrieve is always the element with the greatest value. (This class will be discussed in Chapter 19.)

STL Header Files

Table 17-4 Header Files

Header File	Classes
<code><array></code>	<code>array</code>
<code><deque></code>	<code>deque</code>
<code><forward_list></code>	<code>forward_list</code>
<code><list></code>	<code>list</code>
<code><map></code>	<code>map</code> , <code>multimap</code>
<code><queue></code>	<code>queue</code> , <code>priority_queue</code>
<code><set></code>	<code>set</code> , <code>multiset</code>
<code><stack></code>	<code>stack</code>
<code><unordered_map></code>	<code>unordered_map</code> , <code>unordered_multimap</code>
<code><unordered_set></code>	<code>unordered_set</code> , <code>unordered_multiset</code>
<code><vector></code>	<code>vector</code>

The array Class Template

- An array object works very much like a regular array
- A fixed-size container that holds elements of the same data type.
- array objects have a `size()` member function that returns the number of elements contained in the object.

The array Class Template

- The array class is declared in the <array> header file.
- When defining an array object, you specify the data type of its elements, and the number of elements.
- Examples:

```
array<int, 5> numbers;
```

```
array<string, 4> names;
```

The array Class Template

Initializing an array object:

```
array<int, 5> numbers = {1, 2, 3, 4, 5};
```

```
array<string, 4> names = {"Jamie", "Ashley", "Doug",  
                          "Claire"};
```

The array Class Template

- The `array` class overloads the `[]` operator.
- You can use the `[]` operator to access elements using a subscript, just as you would with a regular array.
- The `[]` operator does not perform bounds checking. Be careful not to use a subscript that is out of bounds.

Program 17-1

```
1  #include <iostream>
2  #include <string>
3  #include <array>
4  using namespace std;
5
6  int main()
7  {
8      const int SIZE = 4;
9
10     // Store some names in an array object.
11     array<string, SIZE> names = {"Jamie", "Ashley", "Doug", "Claire"};
12
13     // Display the names.
14     cout << "Here are the names:\n";
15     for (int index = 0; index < names.size(); index++)
16         cout << names[index] << endl;
17
18     return 0;
19 }
```

Program Output

Here are the names:
Jamie
Ashley
Doug
Claire

Iterators

- Objects that work like pointers
- Used to access data in STL containers
- Five categories of iterators:

Table 17-6 Categories of Iterators

Iterator Category	Description
Forward	Can only move forward in a container (uses the ++ operator).
Bidirectional	Can move forward or backward in a container (uses the ++ and -- operators).
Random access	Can move forward and backward, and can jump to a specific data element in a container.
Input	Can be used with an input stream to read data from an input device or a file.
Output	Can be used with an output stream to write data to an output device or a file.

Similarities between Pointers and Iterators

	Pointers	Iterators
Use the * and -> operators to dereference	Yes	Yes
Use the = operator to assign to an element	Yes	Yes
Use the == and != operators to compare	Yes	Yes
Use the ++ operator to increment	Yes	Yes
Use the -- operator to decrement	Yes	Yes (bidirectional and random- access iterators)
Use the + operator to move forward a specific number of elements	Yes	Yes
Use the - operator to move backward a specific number of elements	Yes	Yes Yes (bidirectional and random- access iterators)

Iterators

- To define an iterator, you must know what type of container you will be using it with.
- The general format of an iterator definition:

containerType::iterator iteratorName;

Where *containerType* is the STL container type, and *iteratorName* is the name of the iterator variable that you are defining.

Iterators

- For example, suppose we have defined an array object, as follows:

```
array<string, 3> names = {"Sarah", "William", "Alfredo"};
```

We can define an iterator that is compatible with the array object as follows:

```
array<string, 3>::iterator it;
```

This defines an iterator named `it`. The iterator can be used with an `array<string, 3>` object.

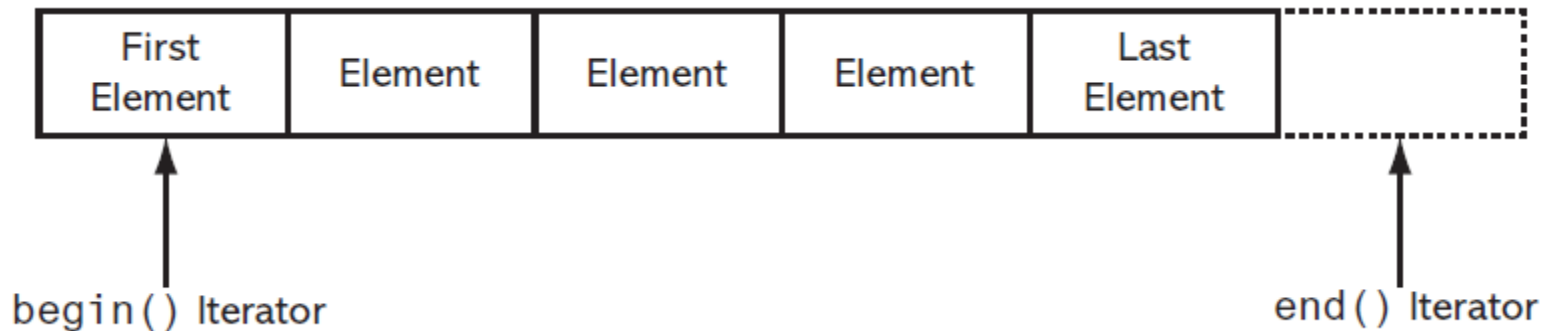

Iterators

- All of the STL containers have a `begin()` member function that returns an iterator pointing to the container's first element.

```
// Define an array object.  
array<string, 3> names = {"Sarah", "William", "Alfredo"};  
  
// Define an iterator for the array object.  
array<string, 3>::iterator it;  
  
// Make the iterator point to the array object's first element.  
it = names.begin();  
  
// Display the element that the iterator points to.  
cout << *it << endl;
```

Iterators

- All of the STL containers have a `end()` member function that returns an iterator pointing to the position *after* the container's last element.

Iterators

- You typically use the `end()` member function to know when you have reached the end of a container.

```
// Define an array object.  
array<string, 3> names = {"Sarah", "William", "Alfredo"};  
  
// Define an iterator for the array object.  
array<string, 3>::iterator it;  
  
// Make the iterator point to the array object's first element.  
it = names.begin();  
  
// Display the array object's contents.  
while (it != names.end())  
{  
    cout << *it << endl;  
    it++;  
}
```

Program 17-2

```
1  #include <iostream>
2  #include <string>
3  #include <array>
4  using namespace std;
5
6  int main()
7  {
8      const int SIZE = 3;
9
10     // Store some names in an array object.
11     array<string, SIZE> names = {"Sarah", "William", "Alfredo"};
12
13     // Create an iterator for the array object.
14     array<string, SIZE>::iterator it;
15
16     // Display the names.
17     cout << "Here are the names:\n";
18     for (it = names.begin(); it != names.end(); it++)
19         cout << *it << endl;
20
21     return 0;
22 }
```

Program Output

Here are the names:
Sarah
William
Alfredo

Iterators

- You can use the auto keyword to simplify the definition of an iterator.
- Example:

```
array<string, 3> names = {"Sarah", "William", "Alfredo"};  
auto it = names.begin();
```

Program 17-3

```
1  #include <iostream>
2  #include <string>
3  #include <array>
4  using namespace std;
5
6  int main()
7  {
8      const int SIZE = 4;
9
10     // Store some names in an array object.
11     array<string, SIZE> names = {"Jamie", "Ashley", "Doug", "Claire"};
12
13     // Display the names.
14     cout << "Here are the names:\n";
15     for (auto it = names.begin(); it != names.end(); it++)
16         cout << *it << endl;
17
18     return 0;
19 }
```

Mutable Iterators

- An iterator of the `iterator` type gives you read/write access to the element to which the iterator points.
- This is commonly known as a mutable iterator.

```
// Define an array object.  
array<int, 5> numbers = {1, 2, 3, 4, 5};  
  
// Define an iterator for the array object.  
array<int, 5>::iterator it;  
  
// Make the iterator point to the array object's first element.  
it = numbers.begin();  
  
// Use the iterator to change the element.  
*it = 99;
```

Constant Iterators

- An iterator of the `const_iterator` type provides read-only access to the element to which the iterator points.
- The STL containers provide a `cbegin()` member function and a `cend()` member function.
 - The `cbegin()` member function returns a `const_iterator` pointing to the first element in a container.
 - The `cend()` member function returns a `const_iterator` pointing to the end of the container.
 - When working with `const_iterators`, simply use the container class's `cbegin()` and `cend()` member functions instead of the `begin()` and `end()` member functions.

Reverse Iterators

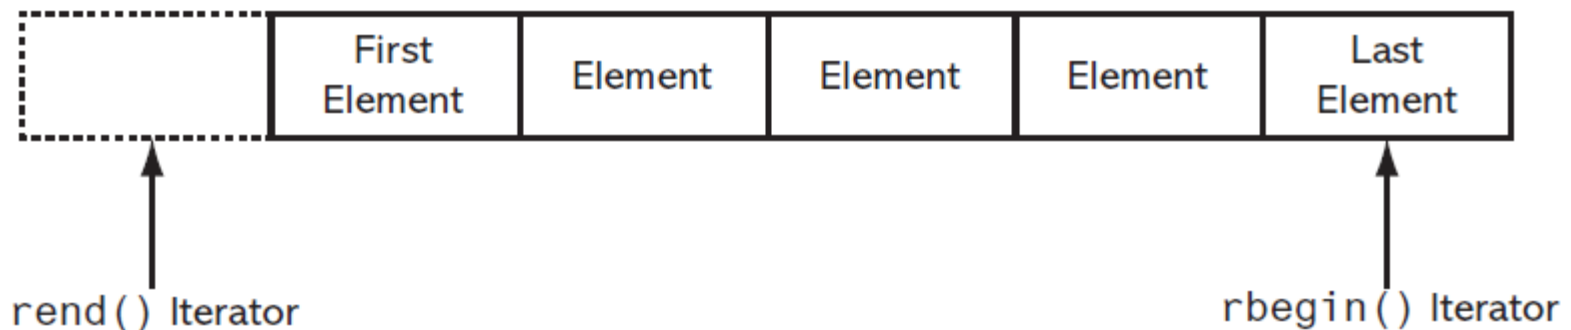

- A *reverse iterator* works in reverse, allowing you to iterate backward over the elements in a container.
- With a reverse iterator, the last element in a container is considered the first element, and the first element is considered the last element.
- The ++ operator moves a reverse iterator backward, and the -- operator moves a reverse iterator forward.

Reverse Iterators

- The following STL containers support reverse iterators:
 - array
 - deque
 - list
 - map
 - multimap
 - multiset
 - set
 - vector
- All of these classes provide an `rbegin()` member function and an `rend()` member function.

Reverse Iterators

- The `rbegin()` member function returns a reverse iterator pointing to the last element in a container.
- The `rend()` member function returns an iterator pointing to the position *before* the first element.

Reverse Iterators

- To create a reverse iterator, define it as `reverse_iterator`

```
// Define an array object.  
array<int, 5> numbers = {1, 2, 3, 4, 5};  
  
// Define a reverse iterator for the array object.  
array<int, 5>::reverse_iterator it;  
  
// Display the elements in reverse order.  
for (it = numbers.rbegin(); it != numbers.rend(); it++)  
    cout << *it << endl;
```

17.3

The vector Class

The vector Class

- A vector is a sequence container that works like an array, but is dynamic in size.
- Overloaded [] operator provides access to existing elements
- The vector class is declared in the `<vector>` header file.

vector Class Constructors

Default Constructor

```
vector<dataType> name;
```

Creates an empty vector.

Fill Constructor

```
vector<dataType> name(size);
```

Creates a vector of *size* elements. If the elements are objects, they are initialized via their default constructor. Otherwise, initialized with 0.

Fill Constructor

```
vector<dataType> name(size, value);
```

Creates a vector of *size* elements, each initialized with *value*.

vector Class Constructors

Range Constructor	<pre>vector<dataType> name(iterator1, iterator2);</pre> <p>Creates a vector that is initialized with a range of values from another container. <i>iterator1</i> marks the beginning of the range and <i>iterator2</i> marks the end.</p>
Copy Constructor	<pre>vector<dataType> name(vector2);</pre> <p>Creates a vector that is a copy of <i>vector2</i>.</p>

Program 17-4

```
1  #include <iostream>
2  #include <vector>
3  using namespace std;
4
5  int main()
6  {
7      const int SIZE = 10;
8
9      // Define a vector to hold 10 int values.
10     vector<int> numbers(SIZE);
11
12     // Store the values 0 through 9 in the vector.
13     for (int index = 0; index < numbers.size(); index++)
14         numbers[index] = index;
15
16     // Display the vector elements.
17     for (auto element : numbers)
18         cout << element << " ";
19     cout << endl;
20
21     return 0;
22 }
```

Subscript notation

Range-based for loop

Program Output

0 1 2 3 4 5 6 7 8 9

Initializing a vector

- In C++ 11 and later, you can initialize a vector object:

```
vector<int> numbers = {1, 2, 3, 4, 5};
```

or

```
vector<int> numbers {1, 2, 3, 4, 5};
```

Adding New Elements to a vector

- The `push_back` member function adds a new element to the end of a vector:

```
vector<int> numbers;  
numbers.push_back(10);  
numbers.push_back(20);  
numbers.push_back(30);
```

Accessing Elements with the `at()` Member Function

- You can use the `at()` member function to retrieve a vector element by its index with bounds checking:

```
vector<string> names = {"Joe", "Karen", "Lisa"};
cout << names.at(0) << endl;
cout << names.at(1) << endl;
cout << names.at(2) << endl;
cout << names.at(3) << endl; // Throws an exception
```

Throws an `out_of_bounds` exception
when given an invalid index

Using an Iterator With a vector

- vectors have `begin()` and `end()` member functions that return iterators pointing to the beginning and end of the container:

```
// Create a vector containing names.
vector<string> names = {"Joe", "Karen", "Lisa", "Jackie"};

// Create an iterator.
vector<string>::iterator it; ← Defines an iterator that is compatible
                               with a vector<string> object

// Use the iterator to display each element in the vector.
for (it = names.begin(); it != names.end(); it++)
{
    cout << *it << endl; ← Displays the item that the iterator points to
}
```

Using an Iterator With a vector

- The `begin()` and `end()` member functions return a random-access iterator of the `iterator` type
- The `cbegin()` and `cend()` member functions return a random-access iterator of the `const_iterator` type
- The `rbegin()` and `rend()` member functions return a reverse iterator of the `reverse_iterator` type
- The `crbegin()` and `crend()` member functions return a reverse iterator of the `const_reverse_iterator` type

Inserting Elements with the `insert()` Member Function

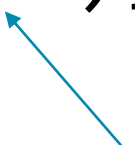

- You can use the `insert()` member function, along with an iterator, to insert an element at a specific position.
- General format:

```
vectorName.insert(it, value);
```

Iterator pointing to an
element in the vector

Value to insert before
the element that *it*
points to

Program 17-5

```
1  #include <iostream>
2  #include <vector>
3  using namespace std;
4
5  int main()
6  {
7      // Define a vector with 5 int values.
8      vector<int> numbers = {1, 2, 3, 4, 5};
9
10     // Define an iterator pointing to the second element.
11     auto it = numbers.begin() + 1;
12
13     // Insert a new element with the value 99.
14     numbers.insert(it, 99);
15
16     // Display the vector elements.
17     for (auto element : numbers)
18         cout << element << " ";
19     cout << endl;
20
21     return 0;
22 }
```

Program Output

1 99 2 3 4 5

Overloaded Versions of the `insert()` Member Function

<code>insert(it, value)</code>	Inserts <i>value</i> just before the element pointed to by <i>it</i> . The function returns an iterator pointing to the newly inserted element.
<code>insert(it, n, value)</code>	Inserts <i>n</i> elements just before the element pointed to by <i>it</i> . Each of the new elements will be initialized with <i>value</i> . The function returns an iterator pointing to the first element of the newly inserted elements.
<code>insert(iterator1, iterator2, iterator3)</code>	Inserts a range of new elements. <i>iterator1</i> points to an existing element in the container. The range of new elements will be inserted before the element pointed to by <i>iterator1</i> . <i>iterator2</i> and <i>iterator3</i> mark the beginning and end of a range of values that will be inserted. (The element pointed to by <i>iterator3</i> will not be included in the range.) The function returns an iterator pointing to the first element of the newly inserted range.

Storing Objects Of Your Own Classes in a vector

- STL containers are especially useful for storing objects of your own classes.
- Consider this Product class:

```
1  #ifndef PRODUCT_H
2  #define PRODUCT_H
3  #include <string>
4  using namespace std;
5
6  class Product
7  {
8  private:
9      string name;
10     int units;
11 public:
12     Product(string n, int u)
13     {   name = n;
14         units = u; }
15
16     void setName(string n)
17     {   name = n; }
18
19     void setUnits(int u)
20     {   units = u; }
21
22     string getName() const
23     {   return name; }
24
25     int getUnits() const
26     {   return units; }
27 };
28 #endif
```

Program 17-7

```
1  #include <iostream>
2  #include <vector>
3  #include "Product.h"
4  using namespace std;
5
6  int main()
7  {
8      // Create a vector of Product objects.
9      vector<Product> products =
10     {
11         Product("T-Shirt", 20),
12         Product("Calendar", 25),
13         Product("Coffee Mug", 30)
14     };
15
16     // Display the vector elements.
17     for (auto element : products)
18     {
19         cout << "Product: " << element.getName() << endl
20             << "Units: " << element.getUnits() << endl;
21     }
22
23     return 0;
24 }
```

This program initializes a vector with three Product objects.

A range-based for loop iterates over the vector.

Program Output

```
Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30
```

Program 17-8

```
1  #include <iostream>
2  #include <string>
3  #include <vector>
4  #include "Product.h"
5  using namespace std;
6
7  int main()
8  {
9      // Create Product objects.
10     Product prod1("T-Shirt", 20);
11     Product prod2("Calendar", 25);
12     Product prod3("Coffee Mug", 30);
13
14     // Create a vector to hold the Products
15     vector<Product> products;
16
17     // Add the products to the vector.
18     products.push_back(prod1);
19     products.push_back(prod2);
20     products.push_back(prod3);
21
22     // Use an iterator to display the vector contents.
23     for (auto it = products.begin(); it != products.end(); it++)
24     {
25         cout << "Product: " << it->getName() << endl
26              << "Units: " << it->getUnits() << endl;
27     }
28
29     return 0;
30 }
```

This program uses the `push_back` member function to store three `Product` objects in a vector.

A for loop uses an iterator to step through the vector.

Program Output

```
Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30
```

Inserting Container Elements With Emplacement

- Member functions such as `insert()` and `push_back()` can cause temporary objects to be created in memory while the insertion is taking place.
- This is not a problem in programs that make only a few insertions.
- However, these functions can be inefficient for making a lot of insertions.

Inserting Container Elements With Emplacement

- C++11 introduced a new family of member functions that use a technique known as *emplacement* to insert new elements.
- Emplacement avoids the creation of temporary objects in memory while a new object is being inserted into a container.
- The emplacement functions are more efficient than functions such as `insert()` and `push_back()`

Inserting Container Elements With Emplacement

- The vector class provides two member functions that use emplacement:
 - `emplace()` - emplaces an element at a specific location
 - `emplace_back()` - emplaces an element at the end of the vector
- With these member functions, it is not necessary to instantiate, ahead of time, the object you are going to insert.
- Instead, you pass to the emplacement function any arguments that you would normally pass to the constructor of the object you are inserting.
- The emplacement function handles the construction of the object, forwarding the arguments to its constructor.

Program 17-9

```
1  #include <iostream>
2  #include <vector>
3  #include "Product.h"
4  using namespace std;
5
6  int main()
7  {
8      // Create a vector to hold Products.
9      vector<Product> products;
10
11     // Add Products to the vector.
12     products.emplace_back("T-Shirt", 20);
13     products.emplace_back("Calendar", 25);
14     products.emplace_back("Coffee Mug", 30);
15
16     // Use an iterator to display the vector contents.
17     for (auto it = products.begin(); it != products.end(); it++)
18     {
19         cout << "Product: " << it->getName() << endl
20             << "Units: " << it->getUnits() << endl;
21     }
22     return 0;
23 }
24 }
```

Define a vector to hold Product objects

Emplace three Product objects at the end of the vector

A for loop uses an iterator to step through the vector.

Program Output

```
Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30
```

Program 17-10

```
1  #include <iostream>
2  #include <vector>
3  #include "Product.h"
4  using namespace std;
5
6  int main()
7  {
8      // Create a vector to hold Products.
9      vector<Product> products =
10     {
11         Product("T-Shirt", 20),
12         Product("Coffee Mug", 30)
13     };
14
15     // Get an iterator to the 2nd element.
16     auto it = products.begin() + 1;
17
18     // Insert another Product into the vector.
19     products.emplace(it, "Calendar", 25);
20
21     // Display the vector contents.
22     for (auto element : products)
23     {
24         cout << "Product: " << element.getName() << endl
25              << "Units: " << element.getUnits() << endl;
26     }
27
28     return 0;
29 }
```

Initializes a vector with two Product objects

Gets an iterator pointing to the 2nd element

Emplaces a new Product object before the one pointed to by the iterator

Program Output

```
Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30
```

The vector Class

- The vector class has many useful member functions.
- See Table 17-8 in your textbook.

17.4

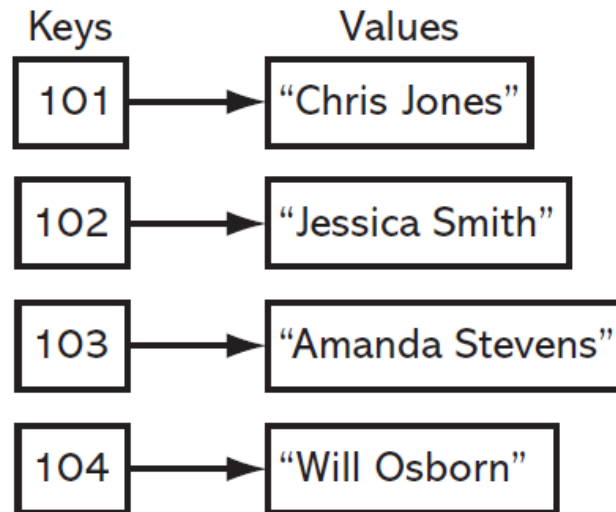

The map, multimap, and unordered_map Classes

Maps – General Concepts

- A *map* is an associative container.
- Each element that is stored in a map has two parts: a *key* and a *value*.
- To retrieve a specific value from a map, you use the key that is associated with that value.
- This is similar to the process of looking up a word in the dictionary, where the words are keys and the definitions are values.

Maps

- Example: a map in which employee IDs are the keys and employee names are the values.
- You use an employee's ID to look up that employee's name.

The map Class

- You can use the STL map class to store key-value pairs.
- The keys that are stored in a map container are unique – no duplicates.
- The map class is declared in the `<map>` header file.

map Class Constructors

Default Constructor `map<keyDataType, valueDataType> name;`
Creates an empty map.

Range Constructor `map<keyDataType, valueDataType>`
 `name(iterator1, iterator2);`
Creates a map that is initialized with a range of values from another map. *iterator1* marks the beginning of the range and *iterator2* marks the end.

Copy Constructor `map<keyDataType, valueDataType> name(map2);`
Creates a map that is a copy of *map2*.

The map Class

- Example: defining a map container to hold employee ID numbers (as ints) and their corresponding employee names (as strings):

```
map<int, string> employees;
```

Key data type

Value data type

Initializing a map

```
map<int, string> employees =  
{  
    {101, "Chris Jones"}, {102, "Jessica Smith"},  
    {103, "Amanda Stevens"}, {104, "Will Osborn"}  
};
```

- In the first element, the key is 101 and the value is "Chris Jones".
- In the second element, the key is 102 and the value is "Jessica Smith".
- In the third element, the key is 103 and the value is "Amanda Stevens".
- In the fourth element, the key is 104 and the value is "Will Osborn".

The Overloaded [] Operator

- You can use the [] operator to add new elements to a map.

- General format:

mapName[key] = value;

- This adds the key-value pair to the map.
- If the key already exists in the map, it's associated value will be changed to *value*.

The Overloaded [] Operator

```
map<int, string> employees;  
employees[110] = "Beth Young";  
employees[111] = "Jake Brown";  
employees[112] = "Emily Davis";
```

- After this code executes, the employees map will contain the following elements:
 - Key = 110, Value = "Beth Young"
 - Key = 111, Value = "Jake Brown"
 - Key = 112, Value = "Emily Davis"

The pair Type

- Internally, the elements of a map are stored as instances of the pair type.
- pair is a struct that has two member variables: first and second.
- The element's key is stored in first, and the element's value is stored in second.
- The pair struct is declared in the <utility> header file. When you #include the <map> header file, <utility> is automatically included as well.

Inserting Elements with the `insert()` Member Function

- The `map` class provides an `insert()` member function that adds a `pair` object as an element to the map.
- You can use the STL function template `make_pair` to construct a `pair` object.
- The `make_pair` function template is declared in the `<utility>` header file.

Inserting Elements with the `insert()` Member Function

```
map<int, string> employees;  
employees.insert(make_pair(110, "Beth Young"));  
employees.insert(make_pair(111, "Jake Brown"));  
employees.insert(make_pair(112, "Emily Davis"));
```

- After this code executes, the `employees` map will contain the following elements:
 - Key = 110, Value = "Beth Young"
 - Key = 111, Value = "Jake Brown"
 - Key = 112, Value = "Emily Davis"

Note: If the element that you are inserting with the `insert()` member function has the same key as an existing element, the function will *not* insert the new element.

Inserting Elements with the `emplace()` Member Function

- The `map` class also provides an `emplace()` member function that adds an element to the map.

```
map<int, string> employees;  
employees.emplace(110, "Beth Young");  
employees.emplace(111, "Jake Brown");  
employees.emplace(112, "Emily Davis");
```

- After this code executes, the `employees` map will contain the following elements:
 - Key = 110, Value = "Beth Young"
 - Key = 111, Value = "Jake Brown"
 - Key = 112, Value = "Emily Davis"

Note: If the element that you are inserting with the `emplace()` member function has the same key as an existing element, the function will *not* insert the new element.

Retrieving Elements with the `at()` Member Function

- You can use the `at()` member function to retrieve a map element by its key:

```
// Create a map containing employee IDs and names.  
map<int, string> employees =  
{  
    {101, "Chris Jones"}, {102, "Jessica Smith"},  
    {103, "Amanda Stevens"}, {104, "Will Osborn"}  
};
```

```
// Retrieve a value from the map.  
cout << employees.at(103) << endl;
```

Displays "Amanda Stevens"

Retrieving Elements with the `at()` Member Function

- To prevent the `at()` member function from throwing an exception (if the specified key does not exist), use the `count` member function to determine whether it exists:

```
// Create a map containing employee IDs and names.
map<int, string> employees =
{
    {101, "Chris Jones"}, {102, "Jessica Smith"},
    {103, "Amanda Stevens"}, {104, "Will Osborn"}
};
```

```
// Retrieve a value from the map.
```

```
if (employees.count(103))
    cout << employees.at(103) << endl;
else
    cout << "Employee not found.\n";
```

← The `count()` member function returns 1 if the specified key exists, or 0 otherwise.

Deleting Elements

- You can use the `erase()` member function to retrieve a map element by its key:

```
// Create a map containing employee IDs and names.  
map<int, string> employees =  
{  
    {101, "Chris Jones"}, {102, "Jessica Smith"},  
    {103, "Amanda Stevens"}, {104, "Will Osborn"}  
};
```

```
// Delete the employee with ID 102.  
employees.erase(102);
```

Deletes Jessica Smith from the map

Stepping Through a map with the Range-Based for Loop

```
// Create a map containing employee IDs and names.  
map<int, string> employees =  
{  
    {101, "Chris Jones"}, {102, "Jessica Smith"},  
    {103, "Amanda Stevens"}, {104, "Will Osborn"}  
};
```

Remember, each element is a pair.

```
// Display each element.  
for (pair<int, string> element : employees)  
{  
    cout << "ID: " << element.first << "\tName: "  
        << element.second << endl;  
}
```

Stepping Through a map with the Range-Based for Loop

```
// Create a map containing employee IDs and names.  
map<int, string> employees =  
{  
    {101, "Chris Jones"}, {102, "Jessica Smith"},  
    {103, "Amanda Stevens"}, {104, "Will Osborn"}  
};
```

```
// Display each element.  
for (auto element : employees) ← auto simplifies this  
{  
    cout << "ID: " << element.first << "\tName: "  
        << element.second << endl;  
}
```

Using an Iterator With a map

- The `begin()` and `end()` member functions return a bidirectional iterator of the `iterator` type
- The `cbegin()` and `cend()` member functions return a bidirectional iterator of the `const_iterator` type
- The `rbegin()` and `rend()` member functions return a reverse bidirectional iterator of the `reverse_iterator` type
- The `crbegin()` and `crend()` member functions return a reverse bidirectional iterator of the `const_reverse_iterator` type

Using an Iterator With a map

- When an iterator points to a map element, it points to an instance of the `pair` type.
- The element has two member variables: `first` and `second`.
- The element's key is stored in `first`, and the element's value is stored in `second`.

Program 17-11

```
1 // This program demonstrates an iterator with a map.
2 #include <iostream>
3 #include <string>
4 #include <map>
5 using namespace std;
6
7 int main()
8 {
9     // Create a map containing employee IDs and names.
10    map<int, string> employees =
11        { {101,"Chris Jones"}, {102,"Jessica Smith"},
12          {103,"Amanda Stevens"},{104,"Will Osborn"} };
13
14    // Create an iterator.
15    map<int, string>::iterator iter;
16
17    // Use the iterator to display each element in the map.
18    for (iter = employees.begin(); iter != employees.end(); iter++)
19    {
20        cout << "ID: " << iter->first
21             << "\tName: " << iter->second << endl;
22    }
23
24    return 0;
25 }
```

Program Output

```
ID: 101 Name: Chris Jones
ID: 102 Name: Jessica Smith
ID: 103 Name: Amanda Stevens
ID: 104 Name: Will Osborn
```

Storing Objects Of Your Own Classes as *Values* in a map

- If you want to store an object as a value in a map, there is one requirement for that object's class:

It must have a default constructor.

- Consider the following Contact class...

```
1  #ifndef CONTACT_H
2  #define CONTACT_H
3  #include <string>
4  using namespace std;
5
6  class Contact
7  {
8  private:
9      string name;
10     string email;
11 public:
12     Contact() ← Default constructor
13     {   name = "";
14         email = ""; }
15
16     Contact(string n, string em)
17     {   name = n;
18         email = em; }
19
20     void setName(string n)
21     {   name = n; }
22
23     void setEmail(string em)
24     {   email = em; }
25
26     string getName() const
27     {   return name; }
28
29     string getEmail() const
30     {   return email; }
31 };
32 #endif
```

Program 17-14

```
1  #include <iostream>
2  #include <string>
3  #include <map>
4  #include "Contact.h"
5  using namespace std;
6
7  int main()
8  {
9      string searchName;    // The name to search for
10
11     // Create some Contact objects
12     Contact contact1("Ashley Miller", "amiller@faber.edu");
13     Contact contact2("Jacob Brown", "jbrown@gotham.edu");
14     Contact contact3("Emily Ramirez", "eramirez@coolidge.edu");
15
16     // Create a map to hold the Contact objects.
17     map<string, Contact> contacts;
18
19     // Create an iterator for the map.
20     map<string, Contact>::iterator iter;
21
22     // Add the contact objects to the map.
23     contacts[contact1.getName()] = contact1;
24     contacts[contact2.getName()] = contact2;
25     contacts[contact3.getName()] = contact3;
```

In the map, the keys are the contact names, and the values are the Contact objects.

```

26
27     // Get the name to search for.
28     cout << "Enter a name: ";
29     getline(cin, searchName);
30
31     // Search for the name.
32     iter = contacts.find(searchName);
33
34     // Display the results.
35     if (iter != contacts.end())
36     {
37         cout << "Name: " << iter->second.getName() << endl;
38         cout << "Email: " << iter->second.getEmail() << endl;
39     }
40     else
41     {
42         cout << "Contact not found.\n";
43     }
44
45     return 0;
46 }

```

Program Output (with Example Input Shown in Bold)

Enter a name: **Emily Ramirez**
 Name: Emily Ramirez
 Email: eramirez@coolidge.edu

Program Output (with Example Input Shown in Bold)

Enter a name: **Billy Clark**
 Contact not found.

Storing Objects Of Your Own Classes as *Keys* in a map

- If you want to store an object as a key in a map, there is one requirement for that object's class:

It must overload the < operator.

- Consider the following Customer class...

```

1  #ifndef CUSTOMER_H
2  #define CUSTOMER_H
3  #include<string>
4  using namespace std;
5
6  class Customer
7  {
8  private:
9      int custNumber;
10     string name;
11 public:
12     Customer(int cn, string n)
13     {   custNumber = cn;
14         name = n; }
15
16     void setCustNumber(int cn)
17     {   custNumber = cn; }
18
19     void setName(string n)
20     {   name = n; }
21
22     int getCustNumber() const
23     {   return custNumber; }
24
25     string getName() const
26     {   return name; }
27
28     bool operator < (const Customer &right) const
29     {   bool status = false;
30
31         if (custNumber < right.custNumber)
32             status = true;
33
34         return status; }
35 };
36 #endif

```

Program 17-17

```
1  #include <iostream>
2  #include <string>
3  #include <map>
4  #include "Customer.h"
5  using namespace std;
6
7  int main()
8  {
9      // Create some Customer objects.
10     Customer customer1(1001, "Sarah Scott");
11     Customer customer2(1002, "Austin Hill");
12     Customer customer3(1003, "Megan Cruz");
13
14     // Create a map to hold the seat assignments.
15     map<Customer, string> assignments;
16
17     // Use the map to store the seat assignments.
18     assignments[customer1] = "1A";
19     assignments[customer2] = "2B";
20     assignments[customer3] = "3C";
21
22     // Display all objects in the map.
23     for (auto element : assignments)
24     {
25         cout << element.first.getName() << "\t"
26              << element.second << endl;
27     }
28
29     return 0;
30 }
```

Program Output

Sarah Scott	1A
Austin Hill	2B
Megan Cruz	3C

This program assigns seats in a theater to customers. The map uses Customer objects as keys, and seat numbers as values.

The unordered_map Class

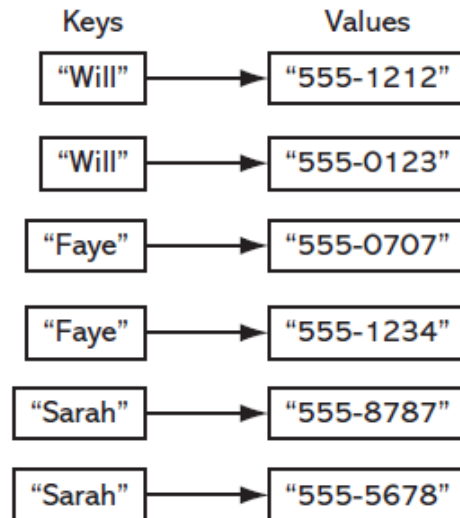

- The unordered_map class is similar to the map class, except in two regards:
 - The keys in an unordered_map are not sorted
 - The unordered_map class has better performance
- You should use the unordered_map class instead of the map class if:
 - You will be making a lot of searches on a large number of elements
 - You are not concerned with retrieving them in key order
- The unordered_map class is declared in the `<unordered_map>` header file

The multimap Class

- The multimap class is a map that allows duplicate keys
- The multimap class has most of the same member functions as the map class (see Table 17-11 in your textbook)
- The multimap class is declared in the `<map>` header file

The multimap Class

- Consider a phonebook application where the key is a person's name and the value is that person's phone number.
- A multimap container would allow each person to have multiple phone numbers

Program 17-19

```
1  #include <iostream>
2  #include <string>
3  #include <map>
4  using namespace std;
5
6  int main()
7  {
8      // Define a phonebook multimap.
9      multimap<string, string> phonebook =
10         { {"Will", "555-1212"}, {"Will", "555-0123"},
11           {"Faye", "555-0707"}, {"Faye", "555-1234"},
12           {"Sarah", "555-8787"}, {"Sarah", "555-5678"} };
13
14     // Display the elements in the multimap.
15     for (auto element : phonebook)
16     {
17         cout << element.first << "\t"
18              << element.second << endl;
19     }
20     return 0;
21 }
```

Program Output

Faye	555-0707
Faye	555-1234
Sarah	555-8787
Sarah	555-5678
Will	555-1212
Will	555-0123

Adding Elements to a multimap

- The multimap class does not overload the `[]` operator.
 - So, you cannot use an assignment statement to add a new element to a multimap.
- Instead, you will use either the `emplace()` or the `insert()` member functions.

Adding Elements to a multimap

```
multimap<string, string> phonebook;  
phonebook.emplace("Will", "555-1212");  
phonebook.emplace("Will", "555-0123");  
phonebook.emplace("Faye", "555-0707");  
phonebook.emplace("Faye", "555-1234");  
phonebook.emplace("Sarah", "555-8787");  
phonebook.emplace("Sarah", "555-5678");
```

Adding Elements to a multimap

```
multimap<string, string> phonebook;  
phonebook.insert(make_pair("Will", "555-1212"));  
phonebook.insert(make_pair("Will", "555-0123"));  
phonebook.insert(make_pair("Faye", "555-0707"));  
phonebook.insert(make_pair("Faye", "555-1234"));  
phonebook.insert(make_pair("Sarah", "555-8787"));  
phonebook.insert(make_pair("Sarah", "555-5678"));
```

Getting the Number of Elements With a Specified Key

- The `multimap` class's `count()` member function accepts a key as its argument, and returns the number of elements that match the specified key.

Program 17-20

```
1  #include <iostream>
2  #include <string>
3  #include <map>
4  using namespace std;
5
6  int main()
7  {
8      // Define a phonebook multimap.
9      multimap<string, string> phonebook =
10         { {"Will", "555-1212"}, {"Will", "555-0123"},
11           {"Faye", "555-0707"}, {"Faye", "555-1234"},
12           {"Sarah", "555-8787"}, {"Sarah", "555-5678"} };
13
14     // Display the number of elements that match "Faye".
15     cout << "Faye has " << phonebook.count("Faye") << " elements.\n";
16     return 0;
17 }
```

Program Output

Faye has 2 elements.

Retrieving Elements with a Specified Key

- The `multimap` class has a `find()` member function that searches for an element with a specified key.
- The `find()` function returns an iterator to the first element matching it.
- If the element is not found, the `find()` function returns an iterator to the end of the `multimap`.

Retrieving Elements with a Specified Key

- To retrieve all elements matching a specified key, use the `equal_range` member function.
- The `equal_range` member function returns a pair object.
 - The pair object's first member is an iterator pointing to the first element that matches the specified key.
 - The pair object's second member is an iterator pointing to the position *after* the last element that matches the specified key.

```
// Define a phonebook multimap.
multimap<string, string> phonebook =
    { {"Will", "555-1212"}, {"Will", "555-0123"},
      {"Faye", "555-0707"}, {"Faye", "555-1234"},
      {"Sarah", "555-8787"}, {"Sarah", "555-5678"} };

// Define a pair variable to receive the object that
// is returned from the equal_range member function.
pair<multimap<string, string>::iterator,
    multimap<string, string>::iterator> range;

// Define an iterator for the multimap.
multimap<string, string>::iterator iter;

// Get the range of elements that match "Faye".
range = phonebook.equal_range("Faye");

// Display all of the elements that match "Faye".
for (iter = range.first; iter != range.second; iter++)
{
    cout << iter->first << "\t" << iter->second << endl;
}
```

Program Output

```
Faye    555-0707
Faye    555-1234
```

Deleting Elements with a Specified Key

- To delete all elements matching a specified key, use the `erase()` member function.

```
// Define a phonebook multimap.
multimap<string, string> phonebook =
    { {"Will", "555-1212"}, {"Will", "555-0123"},
      {"Faye", "555-0707"}, {"Faye", "555-1234"},
      {"Sarah", "555-8787"}, {"Sarah", "555-5678"} };

// Delete Will's phone numbers from the multimap.
phonebook.erase("Will");
```

The unordered_multimap Class

- The unordered_multimap class is similar to the multimap class, except:
 - The keys in an unordered_multimap are not sorted
 - The unordered_multimap class has better performance
- You should use the unordered_multimap class instead of the multimap class if:
 - You will be making a lot of searches on a large number of elements
 - You are not concerned with retrieving them in key order
- The unordered_multimap class is declared in the `<unordered_multimap>` header file

17.5

The set, multiset, and unordered_set Classes

Sets

- A *set* is an associative container that is similar to a mathematical set.
- You can use the STL set class to create a set container.
- All the elements in a set must be unique. No two elements can have the same value.
- The elements in a set are automatically sorted in ascending order.
- The set class is declared in the `<set>` header file.

The set Class

- You can use the STL set class to create a set container.
- The keys that are stored in a map container are unique – no duplicates.
- The map class is declared in the `<map>` header file.

set Class Constructors

Default Constructor `set<dataType> name;`
Creates an empty set.

Range Constructor `set<dataType> name(iterator1, iterator2);`
Creates a set that is initialized with a range of values.
iterator1 marks the beginning of the range and
iterator2 marks the end.

Copy Constructor `set<dataType> name(set2);`
Creates a set that is a copy of *set2*.

The set Class

- Example: defining a set container to hold integers:

```
set<int> numbers;
```

- Example: defining and initializing a set container to hold integers:

```
set<int> numbers = {1, 2, 3, 4, 5};
```

The set Class

- A set cannot contain duplicate items.
- If the same value appears more than once in an initialization list, it will be added to the set only one time.
- For example, the following set will contain the values 1, 2, 3, 4, and 5:

```
set<int> numbers = {1, 1, 2, 2, 3, 4, 5, 5, 5};
```

Adding New Elements to a set

- The `insert()` member function adds a new element to a set:

```
set<int> numbers;  
numbers.insert(10);  
numbers.insert(20);  
numbers.insert(30);
```

Stepping Through a set With the Range-Based for Loop

```
// Create a set containing names.  
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};  
  
// Display each element.  
for (string element : names)  
{  
    cout << element << endl;  
}
```

Using an Iterator With a set

- The `begin()` and `end()` member functions return a bidirectional iterator of the `iterator` type
- The `cbegin()` and `cend()` member functions return a bidirectional iterator of the `const_iterator` type
- The `rbegin()` and `rend()` member functions return a reverse bidirectional iterator of the `reverse_iterator` type
- The `crbegin()` and `crend()` member functions return a reverse bidirectional iterator of the `const_reverse_iterator` type

Using an Iterator With a set

```
// Create a set containing names.
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};

// Create an iterator.
set<string>::iterator iter;

// Use the iterator to display each element in the set.
for (iter = names.begin(); iter != names.end(); iter++)
{
    cout << *iter << endl;
}
```

Determining Whether an Element Exists

- The set class's `count()` member function accepts a value as its argument, and returns 1 if that value exists in the set. The function returns 0 otherwise.

```
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
if (names.count("Lisa"))
    cout << "Lisa was found in the set.\n";
else
    cout << "Lisa was not found.\n";
```

Retrieving an Element

- The set class has a `find()` member function that searches for an element with a specified value.
- The `find()` function returns an iterator to the element matching it.
- If the element is not found, the `find()` function returns an iterator to the end of the set.

Retrieving an Element

```
// Create a set containing names.
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};

// Create an iterator.
set<string>::iterator iter;

// Find "Karen".
iter = names.find("Karen");

// Display the result.
if (iter != names.end())
{
    cout << *iter << " was found.\n";
}
else
{
    cout << "Karen was not found.\n";
}
```

Storing Objects Of Your Own Classes in a set

- If you want to store an object in a set, there is one requirement for that object's class:

It must overload the < operator.

- Consider the following Customer class...

```

1  #ifndef CUSTOMER_H
2  #define CUSTOMER_H
3  #include<string>
4  using namespace std;
5
6  class Customer
7  {
8  private:
9      int custNumber;
10     string name;
11 public:
12     Customer(int cn, string n)
13     {   custNumber = cn;
14         name = n; }
15
16     void setCustNumber(int cn)
17     {   custNumber = cn; }
18
19     void setName(string n)
20     {   name = n; }
21
22     int getCustNumber() const
23     {   return custNumber; }
24
25     string getName() const
26     {   return name; }
27
28     bool operator < (const Customer &right) const
29     {   bool status = false;
30
31         if (custNumber < right.custNumber)
32             status = true;
33
34         return status; }
35 };
36 #endif

```

Program 17-22

```
1  #include <iostream>
2  #include <set>
3  #include "Customer.h"
4  using namespace std;
5
6  int main()
7  {
8      // Create a set of Customer objects.
9      set<Customer> customerset =
10         { Customer(1003, "Megan Cruz"),
11           Customer(1002, "Austin Hill"),
12           Customer(1001, "Sarah Scott")
13         };
14
15     // Try to insert a duplicate customer number.
16     customerset.emplace(1001, "Evan Smith");
17
18     // Display the set elements
19     cout << "List of customers:\n";
20     for (auto element : customerset)
21     {
22         cout << element.getCustNumber() << " "
23              << element.getName() << endl;
24     }
25
```

Continued...

```
26 // Search for customer number 1002.
27 cout << "\nSearching for Customer Number 1002:\n";
28 auto it = customerset.find(Customer(1002, ""));
29
30 if (it != customerset.end())
31     cout << "Found: " << it->getName() << endl;
32 else
33     cout << "Not found.\n";
34
35 return 0;
36 }
```

Program Output

List of customers:

1001 Sarah Scott

1002 Austin Hill

1003 Megan Cruz

Searching for Customer Number 1002:

Found: Austin Hill

The multiset Class

- The multiset class is a set that allows duplicate items.
- The multiset class has the same member functions as the set class (see Table 17-13 in your textbook).
- The multiset class is declared in the `<set>` header file.

The multiset Class

- In the set class, the `count()` member function returns either 0 or 1. In the multiset class, the `count()` member function can return values greater than 1.
- In the set class, the `equal_range()` member function returns a range with, at most, one element. In the multiset class, the `equal_range()` member function can return a range with multiple elements.

The unordered_set Class

- The unordered_set class is similar to the set class, except in two regards:
 - The values in an unordered_set are not sorted
 - The unordered_set class has better performance
- You should use the unordered_set class instead of the set class if:
 - You will be making a lot of searches on a large number of elements
 - You are not concerned with retrieving them in ascending order
- The unordered_set class is declared in the `<unordered_set>` header file

The unordered_multiset Class

- The unordered_multiset class is similar to the multiset class, except in two regards:
 - The values in an unordered_multiset are not sorted
 - The unordered_multiset class has better performance
- You should use the unordered_multiset class instead of the multiset class if:
 - You will be making a lot of searches on a large number of elements
 - You are not concerned with retrieving them in ascending order
- The unordered_multiset class is declared in the `<unordered_set>` header file

17.6

Algorithms

STL Algorithms

- The STL provides a number of algorithms, implemented as function templates, in the `<algorithm>` header file.
- These functions perform various operations on ranges of elements.
- A range of elements is a sequence of elements denoted by two iterators:
 - The first iterator points to the first element in the range
 - The second iterator points to the end of the range (the element to which the second iterator points is not included in the range).

Categories of Algorithms in the STL

- Min/max algorithms
- Sorting algorithms
- Search algorithms
- Read-only sequence algorithms
- Copying and moving algorithms
- Swapping algorithms
- Replacement algorithms
- Removal algorithms
- Reversal algorithms
- Fill algorithms
- Rotation algorithms
- Shuffling algorithms
- Set algorithms
- Transformation algorithm
- Partition algorithms
- Merge algorithms
- Permutation algorithms
- Heap algorithms
- Lexicographical comparison algorithm

Sorting

🍊 The sort function:

```
sort(iterator1, iterator2);
```

iterator1 and *iterator2* mark the beginning and end of a range of elements. The function sorts the range of elements in ascending order.

Searching

The `binary_search` function:

```
binary_search(iterator1, iterator2, value);
```

iterator1 and *iterator2* mark the beginning and end of a range of elements that are sorted in ascending order. *value* is the value to search for. The function returns `true` if *value* is found in the range, or `false` otherwise.

Program 17-23

```
1  #include <iostream>
2  #include <vector>
3  #include <algorithm>
4  using namespace std;
5
6  int main()
7  {
8      int searchValue;    // Value to search for
9
10     // Create a vector of unsorted integers.
11     vector<int> numbers = {10, 1, 9, 2, 8, 3, 7, 4, 6, 5};
12
13     // Sort the vector.
14     sort(numbers.begin(), numbers.end());
15
```

Continued...

```

16     // Display the vector.
17     cout << "Here are the sorted values:\n";
18     for (auto element : numbers)
19         cout << element << " ";
20     cout << endl;
21
22     // Get the value to search for.
23     cout << "Enter a value to search for: ";
24     cin >> searchValue;
25
26     // Search for the value.
27     if (binary_search(numbers.begin(), numbers.end(), searchValue))
28         cout << "That value is in the vector.\n";
29     else
30         cout << "That value is not in the vector.\n";
31
32     return 0;
33 }

```

Program Output

```

Here are the sorted values:
1 2 3 4 5 6 7 8 9 10
Enter a value to search for: 8
That value is in the vector.

```

Program Output

```

Here are the sorted values:
1 2 3 4 5 6 7 8 9 10
Enter a value to search for: 99
That value is not in the vector.

```

Detecting Permutations

- If a range has N elements, there are $N!$ possible arrangements, or permutations, of those elements.
- For example, the range of integers 1, 2, 3 has six possible permutations:

1, 2, 3
1, 3, 2
2, 1, 3
2, 3, 1
3, 1, 2
3, 2, 1

Detecting Permutations

- The `is_permutation()` function determines whether one range of elements is a permutation of another range of elements.

`is_permutation(iterator1, iterator2, iterator3)`

- *iterator1* and *iterator2* mark the beginning and end of the first range of elements.
- *iterator3* marks the beginning of the second range of elements, assumed to have the same number of elements as the first range.
- The function returns `true` if the second range is a permutation of the first range, or `false` otherwise.
- See Program 17-25 in your textbook for an example.

Plugging Your Own Functions into an Algorithm

- Many of the function templates in the STL are designed to accept function pointers as arguments.
- This allows you to “plug” one of your own functions into the algorithm.
- For example:

`for_each(iterator1, iterator2, function)`

- iterator1* and *iterator2* mark the beginning and end of a range of elements.
- function* is the name of a function that accepts an element as its argument.
- The `for_each()` function iterates over the range of elements, passing each element as an argument to *function*.

Plugging Your Own Functions into an Algorithm

🍊 For example, consider this function:

```
void doubleNumber(int &n)
{
    n = n * 2;
}
```

Plugging Your Own Functions into an Algorithm

🍊 And this code snippet:

```
vector<int> numbers = { 1, 2, 3, 4, 5 };
```

```
// Display the numbers before doubling.  
for (auto element : numbers)  
    cout << element << " ";  
cout << endl;
```

This passes each
element of the numbers
vector to the
doubleNumber function.

```
// Double the value of each vector element.  
for_each(numbers.begin(), numbers.end(), doubleNumber);
```

```
// Display the numbers before doubling.  
for (auto element : numbers)  
    cout << element << " ";  
cout << endl;
```

Plugging Your Own Functions into an Algorithm

- Another example:

`count_if(iterator1, iterator2, function)`

- *iterator1* and *iterator2* mark the beginning and end of a range of elements.
- *function* is the name of a function that accepts an element as its argument, and returns either true or false.
- The `count_if()` function iterates over the range of elements, passing each element as an argument to *function*.
- The `count_if` function returns the number of elements for which function returns true.

```
1 #include <iostream>
2 #include <vector>
3 #include <algorithm>
4 using namespace std;
5
6 // Function prototypes
7 bool isNegative(int);
8
9 int main()
10 {
11     // Create a vector of ints.
12     vector<int> numbers = { 0, 99, 120, -33, 10, 8, -1, 101 };
13
14     // Get the number of elements that are negative.
15     int negatives = count_if(numbers.begin(), numbers.end(), isNegative);
16
17     // Display the results.
18     cout << "There are " << negatives << " negative elements.\n";
19     return 0;
20 }
21
22 // isNegative function
23 bool isNegative(int n)
24 {
25     bool status = false;
26
27     if (n < 0)
28         status = true;
29
30     return status;
31 }
```

Program Output

There are 2 negative elements.

Algorithms for Set Operations

- The STL provides function templates for basic mathematical set operations.

STL Function Template	Description
<code>set_union</code>	Finds the union of two sets, which is a set that contains all the elements of both sets, excluding duplicates.
<code>set_intersection</code>	Finds the intersection of two sets, which is a set that contains only the elements that are found in both sets.
<code>set_difference</code>	Finds the difference of two sets, which is the set of elements that appear in one set, but not the other.
<code>set_symmetric_difference</code>	Finds the symmetric difference of two sets, which is the set of elements that appear in one set, but not both.
<code>set_includes</code>	Determines whether one set includes another.

17.7

Introduction to Function Objects and Lambda Expressions

Function Objects

- A function object is an object that acts like a function.
 - It can be called
 - It can accept arguments
 - It can return a value
- Function objects are also known as *functors*

Function Objects

- To create a function object, you write a class that overloads the `()` operator.

```
1  #ifndef SUM_H
2  #define SUM_H
3
4  class Sum
5  {
6  public:
7      int operator()(int a, int b)
8      { return a + b; }
9  };
10 #endif
```

Accepts two int arguments

Returns an int

Program 17-34

```
1  #include <iostream>
2  #include "Sum.h"
3  using namespace std;
4
5  int main()
6  {
7      // Local variables
8      int x = 10;
9      int y = 2;
10     int z = 0;
11
12     // Create a Sum object.
13     Sum sum;
14
15     // Call the sum function object.
16     z = sum(x, y);
17
18     // Display the result.
19     cout << z << endl;
20
21     return 0;
22 }
```

Program Output

12

Anonymous Function Objects

- Function objects can be called at the point of their creation, without being given a name. Consider this class:

```
1  #ifndef IS_EVEN_H
2  #define IS_EVEN_H
3
4  class IsEven
5  {
6  public:
7      bool operator()(int x)
8      { return x % 2 == 0; }
9  };
10 #endif
```

Program 17-36

```
1  #include <iostream>
2  #include <vector>
3  #include <algorithm>
4  #include "IsEven.h"
5  using namespace std;
6
7  int main()
8  {
9      // Create a vector of ints.
10     vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
11
12     // Get the number of elements that even.
13     int evenNums = count_if(v.begin(), v.end(), IsEven());
14
15     // Display the results.
16     cout << "The vector contains " << evenNums << " even numbers.\n";
17     return 0;
18 }
```

An IsEven object is created here, but not given a name. It is anonymous.

Program Output

The vector contains 4 even numbers.

Predicate Terminology

- A function or function object that returns a Boolean value is called a *predicate*.
- A predicate that takes only one argument is called a *unary predicate*.
- A predicate that takes two arguments is called a *binary predicate*.
- This terminology is used in much of the available C++ documentation and literature.

Lambda Expressions

- A lambda expression is a compact way of creating a function object without having to write a class declaration.
- It is an expression that contains only the logic of the object's `operator()` member function.
- When the compiler encounters a lambda expression, it automatically generates a function object in memory, using the code that you provide in the lambda expression for the `operator()` member function.

Lambda Expressions

- General format:

`[](parameter list) { function body }`

- The `[]` is known as the lambda introducer. It marks the beginning of a lambda expression.
- parameter list* is a list of parameter declarations for the function object's `operator()` member function.
- function body* is the code that should be the body of the object's `operator()` member function.

Lambda Expressions

- Example: a lambda expression for a function object that computes the sum of two integers:

```
[(int a, int b) { return x + y; }]
```

Lambda Expressions

- Example: a lambda expression for a function object that determines whether an integer is even is:

```
[](int x) { return x % 2 == 0; }
```

Lambda Expressions

- Example: a lambda expression for a function object that takes an integer as input and prints the square of that integer:

```
[](int a) { cout << a * a << " "; }
```

Lambda Expressions

- When you call a lambda expression, you write a list of arguments, enclosed in parentheses, right after the expression.
- For example, the following code snippet displays 7, which is the sum of the variables x and y:

```
int x = 2;  
int y = 5;  
cout << [](int a, int b) {return a + b;}(x, y) << endl;
```

Lambda Expressions

- The following code segment counts the even numbers in a vector:

```
// Create a vector of ints.  
vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };  
  
// Get the number of elements that are even.  
int evenNums = count_if(v.begin(), v.end(), [](int x) {return x % 2 == 0;});  
  
// Display the results.  
cout << "The vector contains " << evenNums << " even numbers.\n";
```

Lambda Expressions

- Because lambda expressions generate function objects, you can assign a lambda expression to a variable and then call it through the variable's name:

```
auto sum = [](int a, int b) {return a + b;};  
int x = 2;  
int y = 5;  
int z = sum(x, y);
```

Program 17-37

```
1  #include <iostream>
2  #include <vector>
3  #include <algorithm>
4  using namespace std;
5
6  int main()
7  {
8      // Create a vector of ints.
9      vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
10
11     // Use a lambda expression to create a function object.
12     auto isEven = [](int x) { return x % 2 == 0; };
13
14     // Get the number of elements that even.
15     int evenNums = count_if(v.begin(), v.end(), isEven);
16
17     // Display the results.
18     cout << "The vector contains " << evenNums << " even numbers.\n";
19     return 0;
20 }
```

Program Output

The vector contains 4 even numbers.

Functional Classes in the STL

- The STL library defines a number of classes that you can instantiate to create function objects in your program.
- To use these classes, you must `#include` the `<functional>` header file.
- Table 17-15 in your textbook lists a few of the functional classes:

Table 17-15 STL Function Object Classes

Functional Class	Description
<code>less<T></code>	<code>less<T>() (T a, T b)</code> is true if and only if <code>a < b</code>
<code>less_equal<T></code>	<code>less_equal() (T a, T b)</code> is true if and only if <code>a <= b</code>
<code>greater<T></code>	<code>greater<T>() (T a, T b)</code> is true if and only if <code>a > b</code>
<code>greater_equal<T></code>	<code>greater_equal<T>() (T a, T b)</code> is true if and only if <code>a >= b</code>
